
become more low angle interconnected
laminae fine upwards

many pictures of these

This next growth has the largest stroms yet!
1.3 m tall by 70 cm wide
more conical again.
* not sure what to make of it but laterally this surface is a pink mark nonconal laminae breccia tertiary?

generally interconnected
much broader to tall than usual (1/1 across)
by 50 cm tall

11.2 (one of the small ones)

still fine grained

laminae less regular - no longer spherical weathering
very vuggy in between laminae

9.0

at ten become broader again interconnected

9.0m

Slightly smaller around

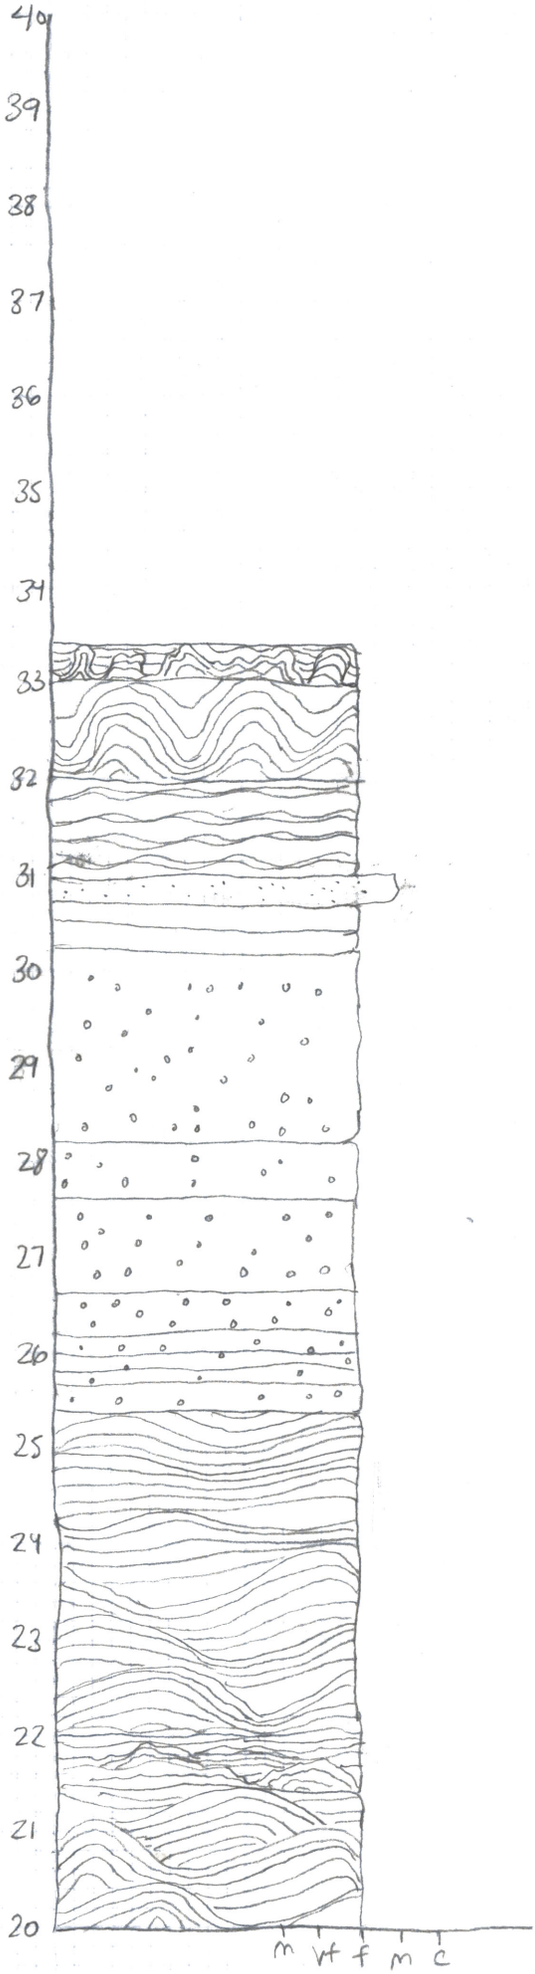
fine grainstone; laminae v. coarse composed of sphere weathering

Stroms get much larger - particularly around. 1.5m across)
(4 cm)
Some very tall and narrow
more continuous; larger
columnar stroms - some quite tall (photo

3.2

sample of round weathering
it looks like matrix is diffent and has grains.

laminae coarse and globular
Small cores (75cm tall x 10 cm wide)
very fine grained; spherical weathering



top of exposure
capped by silicified irreg. stroms

fine grainstone of irregularly laminated domal stroms

ripple fine grainstones

30.8 thin bedded w/ Some coated qtz. grains? sample

29.5

rock is porous; lacy vugs

then into thick massive bedding

transition to thin bedded fine grainstones

24.6

continue low domal stroms w/ irreg. lacy laminae

changes to very irreg. laminae fine grainstone still some stroms

lower domal stroms but still w/ crinkly to like med. laminae
